

Abstract

To provide a portable watch enabling component exchange around a crown when the screw lock capability is reduced. A case band is provided with a pipe-attachment hole opening toward an intracase-band plane and an extracase-band plane, and a pin-receiving groove opening toward this hole, the intracase-band plane, and the extracase-band plane. A winding stem pipe is provided with an intracase-band end section to be arranged inside of the case band including an engagement groove, an extracase-band end section to be arranged outside of the case band including a male screw section to be screwed together with a crown in a removal manner, and a pin-receiving groove opening toward the outer rim plane of the pipe and facing to a receiving groove. The pipe is playably inserted into the hole in a removable manner from the outside of the case band. A rotation-stop pin for preventing the pipe from rotating is placed across both receiving grooves. A pipe stopper for preventing the pipe from being disengaged is engaged to the engagement groove in a removable manner. With such a structure, the crown and the pipe can be separately exchanged.
